ACKNOWLEDGEMENTS

During 2014–15, the Institute of Economic Growth, Delhi had awarded me the Sir Ratan Tata fellowship (Senior Fellow at the level of Associate Professor). This paper was written during that period. I am grateful to Dr. Pravakar Sahoo and Dr. Sabyasachi Kar for their useful remarks. All errors remain my own.

Vighneswara Swamy is Professor, IBS, Hyderabad.

The Dynamics of Government Debt and Economic Growth

ABSTRACT

The dynamics of government debt and economic growth, once a subject of interest to very few macroeconomists, is suddenly of immense attention for many researchers in the backdrop of the Eurozone sovereign debt crisis and of related research by Reinhart and Rogoff. This study investigates the government debt–growth relationship and contributes to the literature in the following ways. First, we extend the horizon of analysis to several country groupings and make the study inclusive of economic, political, and regional diversities—based on a sizeable dataset. Second, we provide evidence for the presence of a causal link going from debt to growth with the use of 'instrumental variables approach', unlike Reinhart and Rogoff's approach. Third, we overcome the issues related to data adequacy, coverage of countries, heterogeneity, endogeneity, and non-linearities by conducting a battery of robustness tests. We find that a 10-percentage-point increase in the debt-to-GDP ratio is associated with 2–23 basis point reduction in average growth. Our results establish the non-linear relationship between debt and growth.

Keywords: Government debt, economic growth, panel data, non-linearity, country groupings

JEL Classification: C33, C36, E62, O5, O40, H63

1 INTRODUCTION

Do sovereign countries with high government debt tend to grow slowly? This has been an important policy question in recent times. As the current debt trajectories in several economies around the world are not sustainable, there is a growing concern among the policymakers, central banks, and international policy organisations to understand the effects of government debt on economic growth. Many countries in the Eurozone and, more particularly, Greece are struggling with a combination of high levels of indebtedness, budget deficits, and frail growth. This has necessitated the revival of the academic and policy debate on the impact of rising levels of government debt on economic growth.

A growing empirical literature shows that there is a negative correlation between government debt and economic growth. This correlation becomes particularly strong when government debt approaches 100 per cent of GDP (Reinhart and Rogoff 2010a, 2010b; Kumar and Woo 2010; Cecchetti et al. 2011). In some of their influential articles, Reinhart and Rogoff argue that higher levels of government debt are negatively correlated with economic growth, but that there is no link between debt and growth when government debt is below 90 per cent of GDP (Reinhart and Rogoff, 2010a; Reinhart, Reinhart and Rogoff 2012). They deftly state that their results did not prove the existence of a causal relationship going from debt to growth. Reinhart and Rogoff's findings have kindled a new literature seeking to assess whether their results were robust enough to allow for non-arbitrary debt brackets, control variables in a multivariate regression setup, reverse causality, and cross-country heterogeneity. After the publication of the (critique) article by Herndon, Ash, and Pollin (2014) challenging some of Reinhart and Rogoff's findings, the discussion on the relationship between debt and growth in advanced economies has become more animated. Krugman (2010), citing the case of Japan, argues that the link between debt and growth could be driven by the fact that it is low economic growth that leads to high levels of government debt.

Empirical research, of late, has begun to focus on the possibility of non-linearities within the debt-growth nexus, with specific attention to high government debt levels. The empirical literature on this issue remains sparse as very few studies employ non-linear impact analysis. Studies by Chang and Chiang (2009), Cecchetti et al., (2011), and Baum et al., (2013) provide some contribution in this direction. Chang and Chiang (2009) and Cecchetti et al., (2011) employ non-linear panel threshold approach for non-dynamic panels.

We notice three inadequacies in the empirical literature on debt-growth nexus. First, none of the studies has focused on the different groupings of economies based on their political structures, income levels, regional geographies, and debt regimes. Second, we do not find studies emphasising the need for establishing the presence of a causal link going from debt to growth that requires finding what economists call an 'instrumental variable'. Third, there is a need to expand the horizon of the data sample, as averaging across OECD / advanced countries alone would make such inferences difficult.

Our study is unique, as it overcomes the issues related to data adequacy, coverage of countries, heterogeneity, endogeneity, and non-linearities. We contribute to the current strand of literature on government debt and economic growth by extending the horizon of analysis to several country groupings and make the study inclusive of economic, political and regional diversities. We provide a thorough econometric analysis of countries with large sample drawn from diverse groupings that allows for non-linearity estimation. Our data-intensive approach offers stylised facts, well beyond the selective anecdotal evidence. We offer to provide evidence for the presence of a causal link going from debt to growth with the use of 'instrumental variables approach' unlike Reinhart and Rogoff's approach. This paper makes a distinct contribution to the debate by offering new empirical evidence based on a sizeable dataset.

The paper is organised as follows. We present our data in Section 2. In Section 3, we analyse the government debt-economic growth nexus. Section 4 describes our estimation strategy. In Section 5, we provide the detailed discussion on results. Section 6 concludes.

2 DATA

Our dataset comprises annual macroeconomic data on 252 countries, over the period 1960-2009. To maintain homogeneity, inasmuch as it is for a large sample of countries over the course of five decades, we employ the World Development Indicators (WDI) database 2014 of the World Bank as a primary source, and strengthen it by using supplementary data sourced from the International Monetary Fund, World Economic Outlook 2014 database, International Financial Statistics and data files, and Reinhart and Rogoff's dataset on debt-to-GDP ratios.

We have grouped our sample data into (1) debt regimes, (2) economy, (3) income, (4) political governance, and (5) region. We place each of the 252 countries in the WDI list into its relevant category of our country groupings. However, each country's entry in the group is dependent on the data adequacy. Exclusion of any country of the WDI list from our sampling is solely due to data considerations (either non-availability or inadequacy of data). Further, for lack of complete data for the stated variables for all the required time period in executing the panel GMM IV approach based regressions, some of the countries could not make it into the detailed econometric analyses of the debt-growth nexus. The list of countries covered in detail under different groupings and sub-groupings are provided in Annexures 1 to 5.

Debt regime groupings

We group our sample countries into five debt regime groupings: 0–30 per cent, 31–60 per cent, 61–90 per cent, 91–150 per cent, and >151 per cent, comparable to Reinhart and Rogoff's groupings based on the average debt/GDP levels (Table 1).

Table 1 Sample description for debt regimes**Panel A** Sample frame for debt regime groupings

Period	DR (%)					Total
	0-30	31-60	61-90	91-150	151 & above

Total=76	1520					

Economy Groupings

The World Economic Outlook April 2011 of IMF¹ guides our classification of countries into advanced, emerging, and developing economies. We consider two more broad groupings: BRICS (Brazil, Russia, India, China, and South Africa) and OECD² (Organisation for Economic Co-operation and Development). Table 2 provides the sample description for economy groupings.

Table 2 Sample description for economy groupings**Panel A** Sample frame for economy groupings

34	680	Middle-income countries (MIC)	3.72%	4.56%	52.17	42.73
Total=111	2220					

Income Groupings

In arranging the data for income groupings, we follow the World Bank classification of economies³ updated for the fiscal year 2015. We consider high-income economies (HIC),

³World Bank country classification is available at <http://data.worldbank.org/about/country-and-lending-groups>. Accordingly, low income countries are those with gross national income (GNI) per capita of \$1,045 or less; middle income countries, \$1,046–12,745; high-income countries, \$12,746 or more. The least developed countries (LDC) are classified as per the criteria set by the United Nations Economic and Social Council Details available at http://www.un.org/en/development/desa/policy/wesp/wesp_current/2014_wesp_country_classification.pdf. Heavily indebted poor countries (HIPC) are classified according to the World Bank and IMF as part of their debt-relief initiative. These classifications are detailed in the World Economic Situation and Prospects (WESP) 2014 of the United Nations employed to delineate trends in various dimensions of the world economy. Also, refer Handbook on the Least Developed Country Category: Inclusion, Graduation and Special Support Measures (United Nations publication). Available from <http://www.un.org/esa/analysis/devplan/cdppublications/2008cdphandbook.pdf>

heavily indebted poor countries (HPC), least developed countries (LDC), low-income economies (LIC), and middle-income economies (MIC). Table 3 provides the description of our sample based on income groupings.

Political governance groupings

We consider seven well acknowledged types of political governance systems; coalition-governments countries (CC), dictator-led countries (DC), federal democracies (FD), Islamic countries (IC), monarchy countries (MC), parliamentary democracies (PD), and socialist/communist countries (SC). In doing so, we are guided by the World Factbook of CIA⁴ and Encyclopedia Britannica. Table 4 provides the description of our sample based on political economy considerations.

Table 4 Sample description for political governance groupings

Panel A Sample frame for political governance groupings

Period	Socialist or Communist Countries (SC)	Dictator led Countries (DC)	Coalition Countries (CC)	Monarchy Countries (MC)	Islamic Countries (IC)	Parliamentary Democracies (PD)	Federal Democracies (FD)	Total
1960-2009	2	12	54	4	23	45	21	161
1970-2009	2	12	54	4	23	45	21	161

Regional groupings

The fifth of our groupings is based on geographical considerations. We consider six broad classifications—Africa, Asia, Europe, North America, Oceania, and South America. In doing so, we follow the classifications detailed in the publication of United Nations Statistics Division⁵. Table 5 provides the description of our sample based on regional groupings.

Table 5 Sample description for regional groupings

Panel A Sample frame for regional groupings

Period	Asia	South America	North America	Europe	Africa	Oceania	Total
1960-2009	25	16	10	39	27	5	122
1970-2009	25	16	10	39	27	5	122
1980-2009	25	16	10	39	27	5	122
1990-2009	25	16	10	39	27	5	122
2000-2009	24	17	9	36	18	3	107

Panel B Sample description for regional groupings

Countries	Observations	Regions	GDP Growth		Government Debt	
			Mean	Median	Mean	Median
21	420	Africa	3.35%	3.92%	91.94	80.08
19	380	Asia	4.49%	5.18%	57.36	52.23
34	680	Europe	1.99%	2.92%	55.04	51.47
7	140	North America	3.50%	3.47%	57.45	54.85
4	80	Oceania	2.92%	3.14%	42.39	43.87
15	300	South America	3.66%	3.96%	69.25	45.66
Total=100	2000					

Subsampling

We explore the dimension of historical specificity by examining real GDP growth by government debt category for subsampled periods of the data: 1960-2009, 1970-2009, 1980-2009, 1990-2009, and 2000-2009. We do not extend our dataset beyond 2009, in view of the sudden and significant rise in government debt levels consequent to the government interventions in response to global financial crisis.⁶

⁵ United Nations Statistics Division - Standard Country and Area Codes Classifications (M49). Details available at <http://unstats.un.org/unsd/methods/m49/m49regin.htm>

⁶ In industrial countries, government debt has risen significantly. In 2009, the net sovereign borrowing needs of the United Kingdom and the United States were five times larger than the average of the preceding five years (2002–07). The huge stimulus and bailout package adopted by the US government to deal with the crisis delivered by irresponsible financial agents in 2009 took the net government debt to GDP ratio in the U.S. from 42.6 in 2007 to 72.4 percent in 2011. In advanced economies as a whole, government debt to GDP ratios are expected to reach 110 percent by 2015—an increase of almost 40 percentage points over pre-crisis levels (IMF 2010). Many middle-income countries also witnessed a deterioration of their debt positions, although the trends are not as dramatic as those of advanced economies are. In low-income countries, in 2009–10 the present value of the government debt to GDP ratio has deteriorated by 5–7 percentage points compared with pre-crisis projections (IDA and IMF 2010).

Figure 1 Debt in debt regimes

This figure illustrates the trend of government debt in debt regimes (0-30; 31-60; 61-90; 91-150; 151 and above). We notice a rising trend of debt with a median of 27.79 percent of GDP in DR 0-30. We find a flat trend with a median at 45 in DR 31-60. A decreasing trend is noticed in DR 61-90 with the median level at 82.87. DR 91-150 has a declining trend with a median of 116.51. In DR 151 & above, we notice the trend like an inverted crescent shape with a median of 160.99.

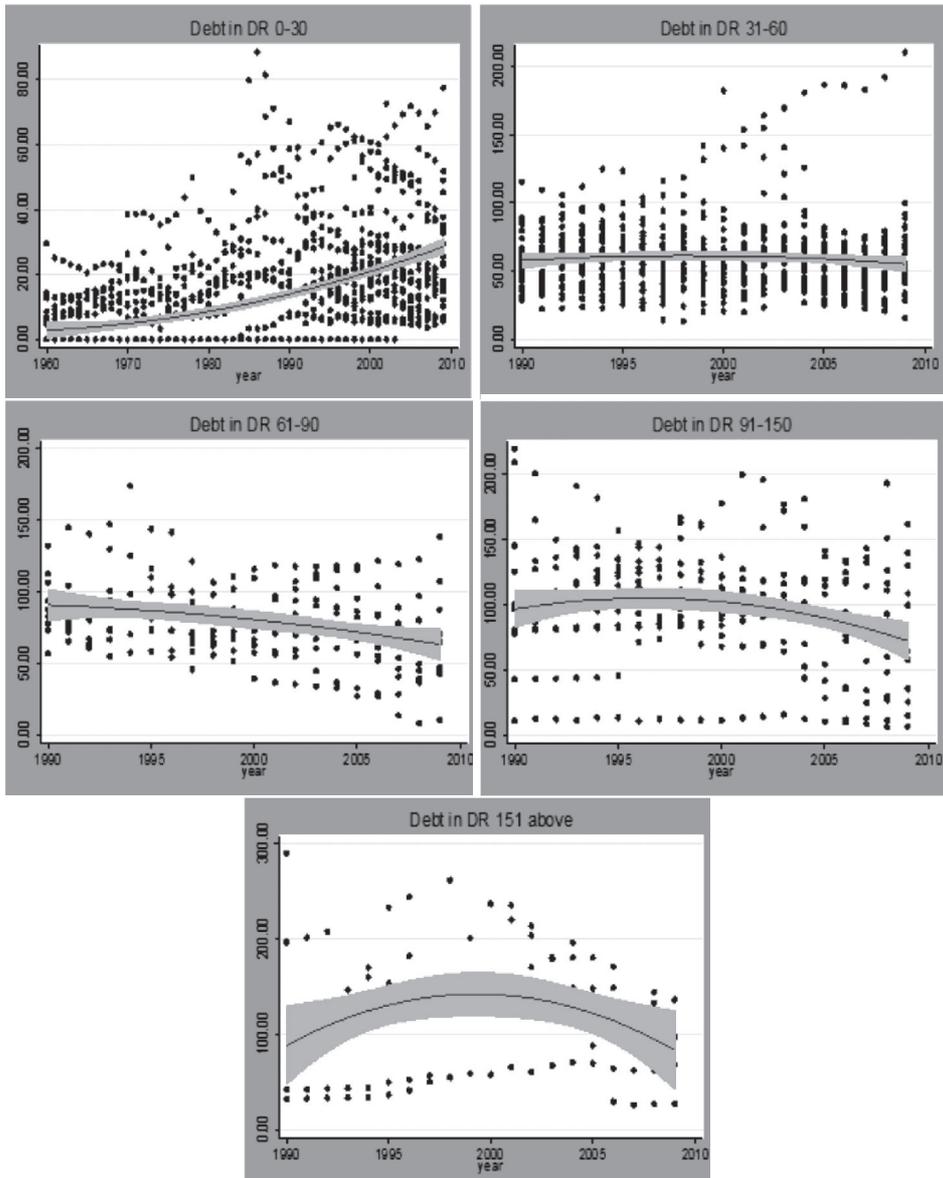

Figure 2 Debt in economy groupings

This figure presents the trend of debt in the economy groupings of sovereign countries. Debt in advanced economies (with a median 53.38) and BRICS economies (46.79) is rising. Developing countries (56.67) and emerging economies (41.35) do not experience a rising trend of debt. However, the trend of debt in OECD countries (51.61) appears to be flat since 1990.

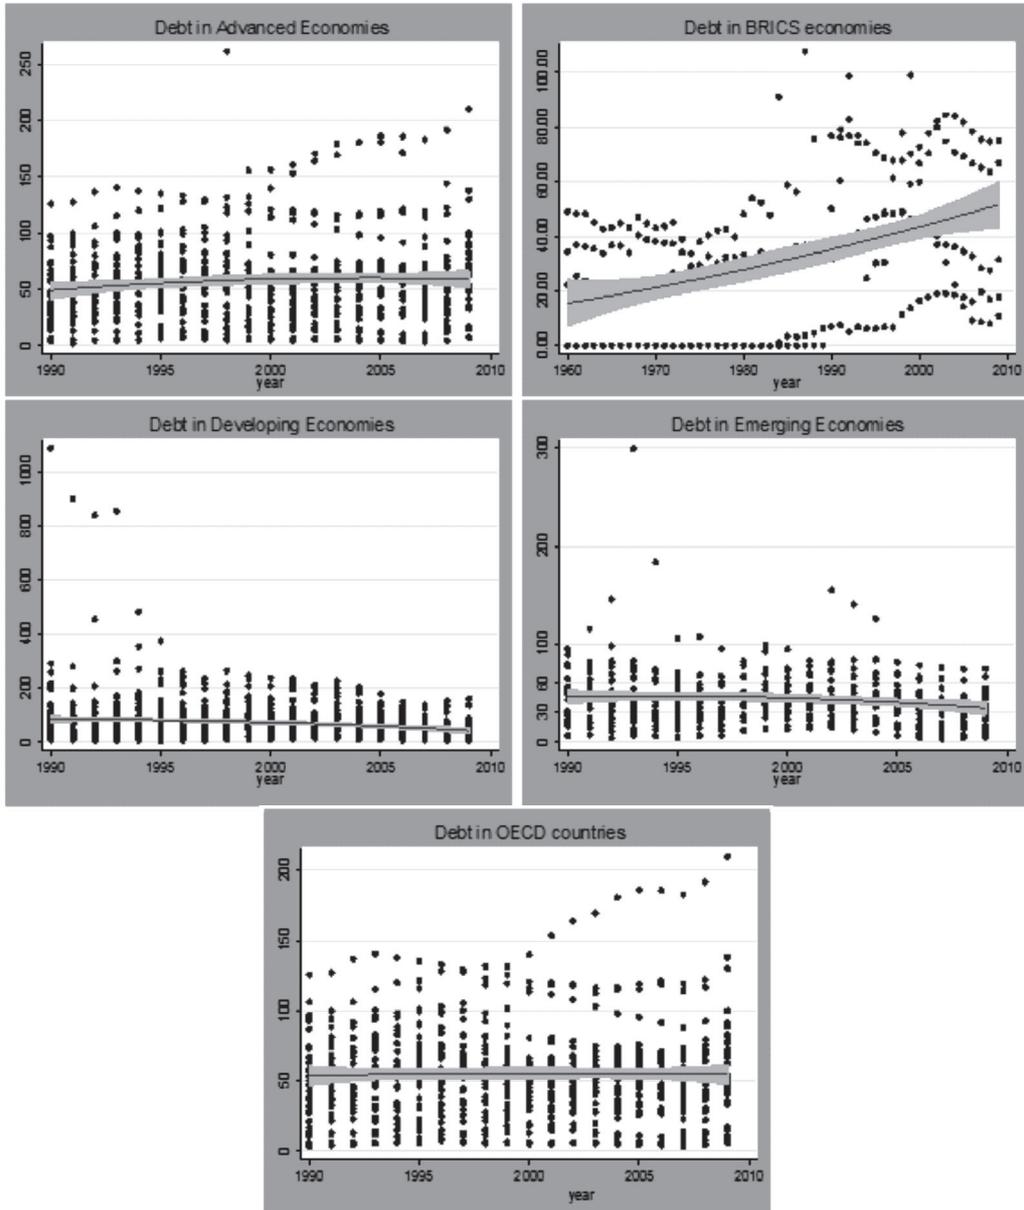

Figure 3 Debt in income groupings

This figure presents the trend of debt in the income groupings of sovereign countries. Debt in high-income countries (HIC) (with a median 45.89) is very slowly rising. Heavily indebted poor countries (HPC) (103.87) group is experiencing a declining trend. Least developed countries (LDC) (81.39) show a gentle decline since 2005. Low-income countries (LIC) (87.06) show the trend like an inverted crescent shape. Middle-income countries (MIC) (42.73) confirm a mild declining trend.

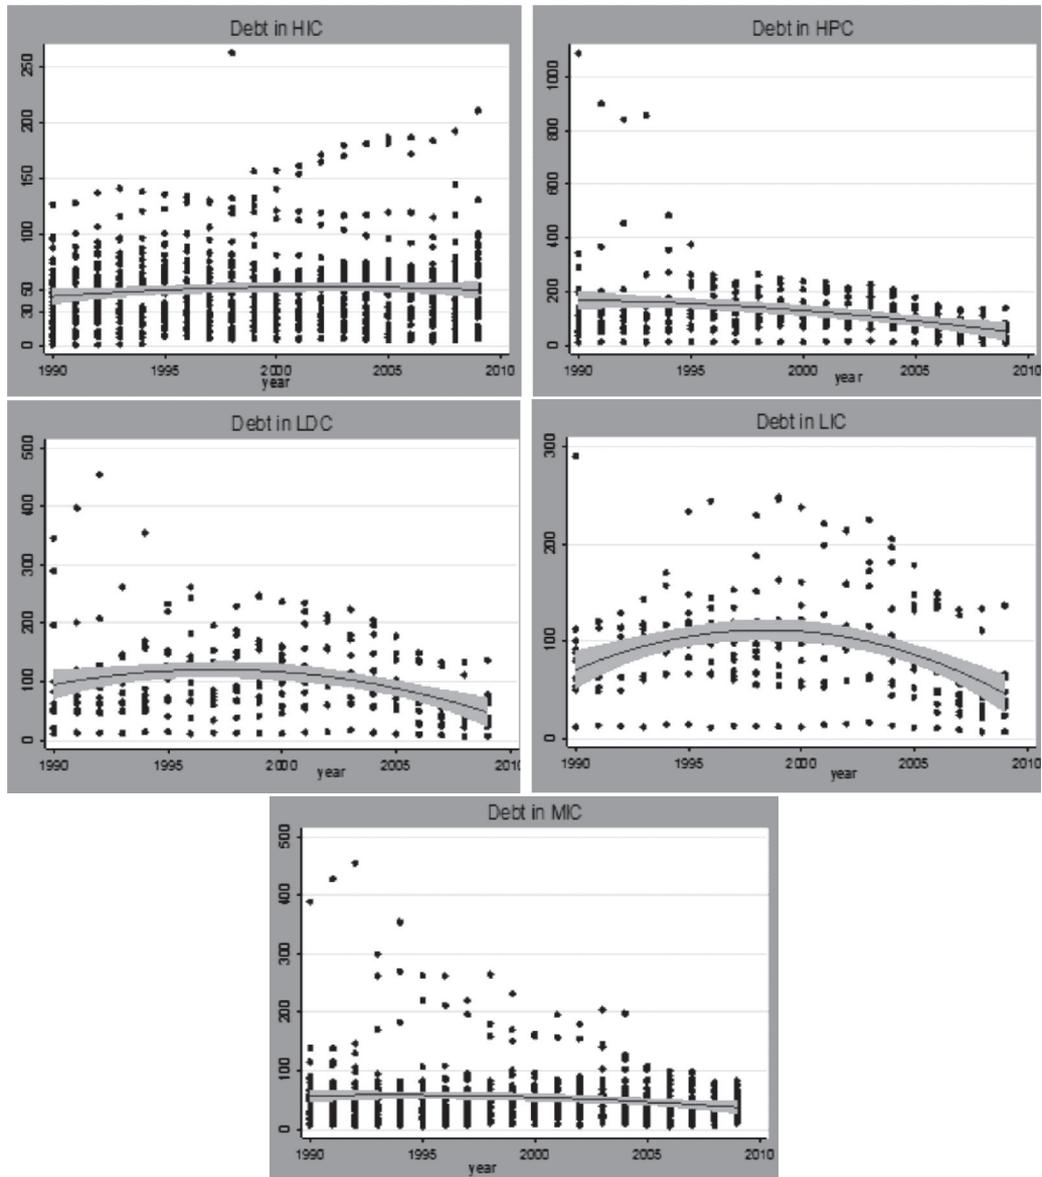

Figure 4 Debt in political governance groupings

This figure presents the trend of debt in the political governance groupings of sovereign countries. The trend of debt in coalition countries (CC) (with a median 61.59) is almost flat. Dictator led countries (DC) (69.63) show a declining trend. Federal democracies (FD) (54.83) and parliamentary democracies (PD) (65.12) display almost a plane trend of debt. Islamic countries (IC) (64.76), monarchy countries (MC) (23.61), and socialist/communist countries (SC) (18.74) show a declining trend of debt.

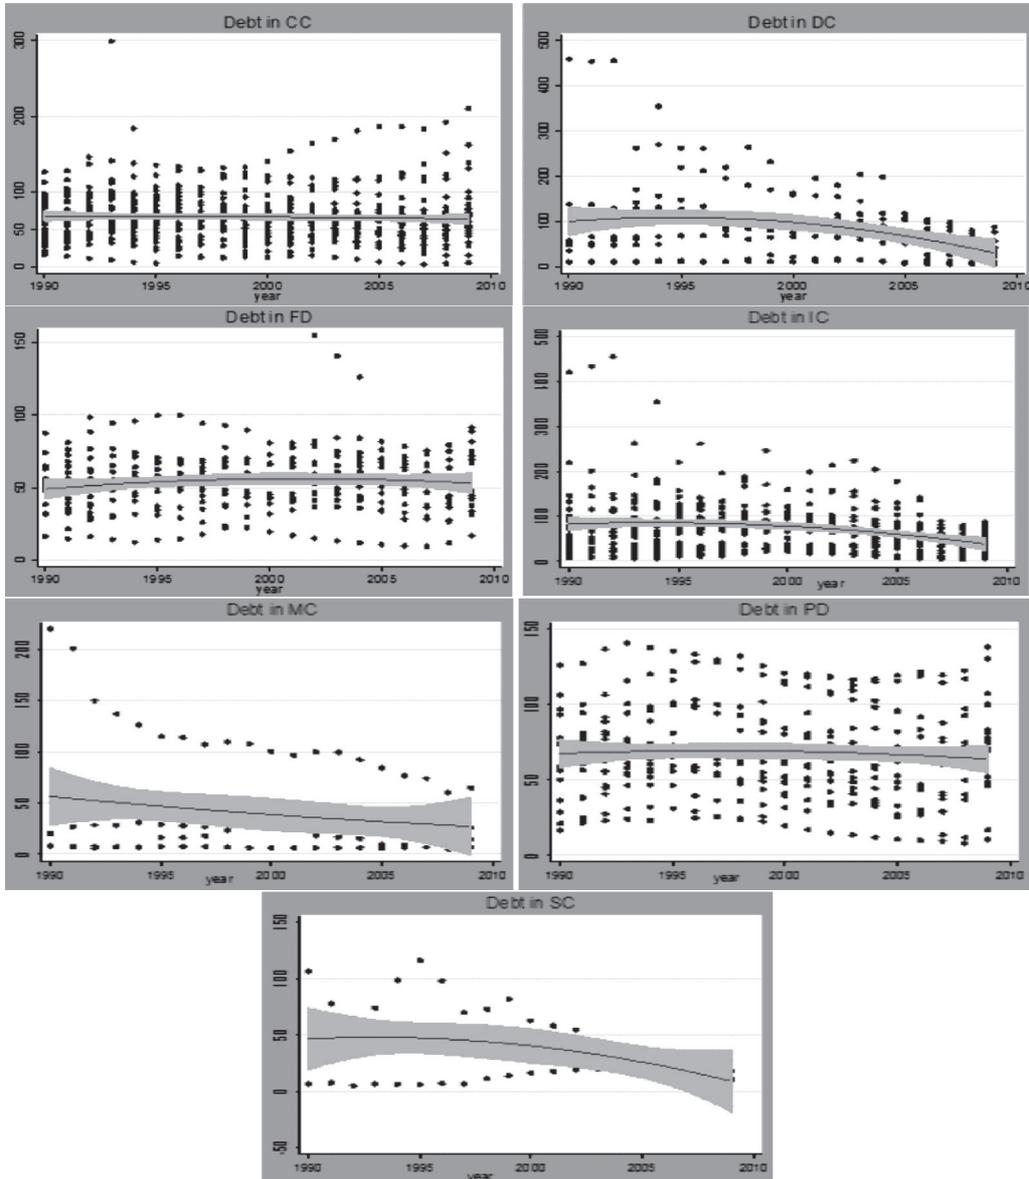

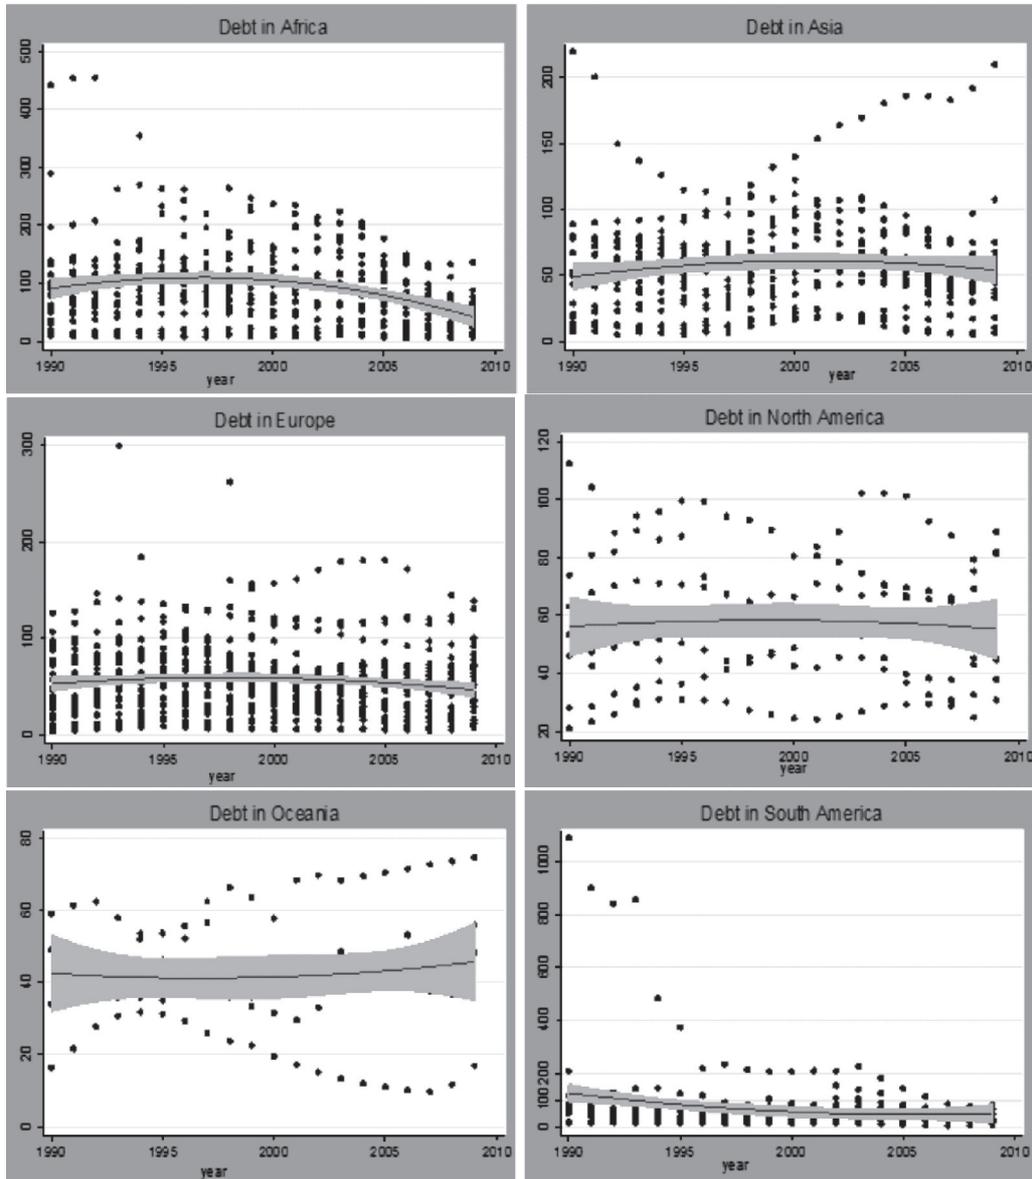

Figure 5: Debt in Regional groupings

This figure presents the trend of debt in the regional groupings of sovereign countries based on their geographies. Africa (median 80.08) with higher levels of debt shows a declining trend. Asia (52.23) and Europe (51.47) show a mildly growing trend of debt. The trend of debt in North America (54.85) appears to be flat. Oceania (43.87) with fewer countries shows a smoothly rising trend of debt. South America (45.66) with few of its countries experiencing very high debt levels displays decreasing trend.

Variables

We provide in Table 6 the description of variables and data sources.

Table 6 Description of variables and data sources

Variable	Description
adr Age dependency ratio (% of working age population)	Age dependency ratio is the ratio of dependents--people younger than 15 or older than 64--to the working-age population--those ages 15-64 Data are shown as the proportion of dependents per 100 working-age population. Source: World Development Indicators (WDI).
fce Final consumption expenditure (% of GDP)	Final consumption expenditure is the sum of household final consumption expenditure (private consumption) and general government final consumption expenditure (general government consumption) Source: WDI.
fdi Foreign direct investment net inflows (% of GDP)	Foreign direct investments are the net inflows of investment to acquire a lasting management interest (10 percent or more of voting stock) in an enterprise operating in an economy other than that of the investor Source: WDI.
gdpgr (GDP growth) Real GDP growth (annual %)	Annual percentage growth rate of GDP at market prices based on constant local currency. Source: WDI.
gfc General government final consumption expenditure (annual % growth)	Annual percentage growth of general government final consumption expenditure based on constant local currency. Source: WDI.
gfcf Gross fixed capital formation (annual % growth)	Average annual growth of gross fixed capital formation based on constant local currency. Source: WDI.
ggd (debt) General government gross debt	Gross debt consists of all liabilities that require payment or payments of interest and/or principal by the debtor to the creditor at a date or dates in the future. This includes debt liabilities in the form of SDRs, currency and deposits, debt securities, loans, insurance, pensions and standardized guarantee schemes, and other accounts payable Source: World Economic Outlook (WEO) April 2012; Reinhart and Rogoff (RR) data set.
infl Inflation (annual %)	Inflation as measured by the annual growth rate of the GDP implicit deflator shows the rate of price change in the economy as a whole. Source: WDI
pg Population growth (annual%)	Annual population growth rate for year t is the exponential rate of growth of midyear population from year t-1 to t, expressed as a percentage. Source: WDI.
rir Real interest rate (%)	Real interest rate is the lending interest rate adjusted for inflation as measured by the GDP deflator. Source: WDI.
tgdp (openness) Trade (% of GDP)	Trade is the sum of exports and imports of goods and services measured as a share of gross domestic product. Source: WDI.
ulf Unemployed labour force	Unemployment, total (% of total labor force) (national estimate). Unemployment refers to the share of the labor force that is without work but available for and seeking employment. Definitions of labor force and unemployment differ by country. Source: WDI.

3 THE DEBT – GROWTH NEXUS

In economic theory, at moderate levels of government debt, following typical Keynesian behaviour, fiscal policy may induce growth. The classical economic view is that government debt (manifesting deficit financing) can induce growth by stimulating aggregate demand and output in the short run. Moderate levels of debt are found to have a positive impact on economic growth through a range of channels: improved monetary policy, strengthened institutions, enhanced private savings, and deepened financial intermediation (Abbas and Christensen 2007). On the other hand, it is argued that government debt crowds out capital and leads to a slowdown of output in the long run (Elmendorf and Mankiw 1999). Historically, the theoretical literature argues that growth models amplified with governments issuing debt to fund consumption or capital goods tend to exhibit a negative relationship between government debt and economic growth. Modigliani (1961) argues that government debt is a burden for the posterity that results in waning flow of income from a reduced stock of private capital.

Both the neoclassical and endogenous growth models inform of the negative effect of government debt on long-term growth. Government debt could have a substantial adverse effect on economic outcomes if it affects the productivity of public expenditures (Teles and Cesar Mussolini 2014). Analysing the impact of fiscal policy—proxied inter alia by the level of government debt—in endogenous growth models, Aizenman et al., (2007) find a negative relationship. Standard growth theory advocates that an increase in government debt (due to a fiscal deficit) leads to slower growth. On the other hand, the neoclassical growth theory suggests a temporary decline in growth along the transition path to a new steady state. However, the endogenous growth theory suggests a permanent decline in growth as the debt increases (Saint-Paul 1992).

Government debt could be used to smoothen distortionary taxation over time (Barro 1979). Barro's model predicts that debt responds to the temporary deviation in income or government expenditure and hence, in the absence of aggregate uncertainty, debt would be constant and equal to its 'initial' level. Though appealing as a normative theory, Barro's model is incompatible to two situations: (1) debt-to-GDP levels in the US display mean-reversion, which implies the existence of a fundamental long-term level of debt; (2) evidence from war episodes suggests temporary increases in expenditure are financed with a mix of instruments, including taxes. Expansionary fiscal policies that lead to debt accumulation are argued to have a positive effect on both short and long-term growth (DeLong and Summers 2012). In a theoretical model integrating the government budget constraint and debt financing, Adam and Bevan (2005) find an increase in growth during low debt levels as they observe interaction effects between deficits and debt stocks, with high debt stocks exacerbating the adverse consequence of high deficits.

Empirical literature on this topic is growing (see, for example, Reinhart and Rogoff (2010), Kumar and Woo (2010), Cecchetti et al. (2011), and Baum et al. (2013)). Several studies report a negative non-linear correlation between public debt and economic growth in advanced and emerging market economies (Reinhart and Rogoff, 2010; (Reinhart and Rogoff 2010; Reinhart et al. 2012; Kumar and Woo 2010; Cecchetti et al. 2011; Checherita-Westphal and Rother 2012)). Though there is growing evidence that government debt is negatively correlated with economic growth, very few studies make a strong case for a causal relationship from debt to growth. Some authors (for example, Panizza and Presbitero (2014)) offer a causal interpretation of their findings and use the debt–growth link as an argument for fiscal consolidation. Using data on 20 developed countries, Lof and Malinen (2014) estimate panel vector auto regressions to analyse the relationship between government debt and economic growth, and find no evidence for a robust effect of debt on growth, even for higher levels of debt. However, they observe significant negative correlation due to reverse effect of growth on debt. This study intends to provide a thorough analysis based on diverse country groups and a wider data set.

4 ESTIMATION STRATEGY

We embark on a multi-step approach to explore our secular dataset covering the period from 1960 to 2009 and thoroughly investigate the nexus between government debt and growth. We employ both the descriptive statistics approach (as relied upon by Reinhart and Rogoff (2010) in their influential paper) and econometric approach to illustrate the debt – growth nexus.

4.1 Testing the bivariate relationship

In our econometric approach to address the topic, we begin by probing the bivariate linear relationship between debt and growth with the following specification:

$$GDPgrowth_t^j = \alpha + \beta debt_t^j + \varepsilon_t \quad \text{----- Eqn (1)}$$

Where $GDPgrowth_t^j$ is the annual GDP growth and $debt_t^j$ is the outstanding gross government debt to GDP ratio for country 'j' in year 't'. We estimate the Eqn (1) with a pooled panel and with country fixed effects.

4.2 Testing the linear relationship

We probe the linear relationship with an econometric specification based on the empirical growth literature (e.g. Barro and Sala-i-Martin 2004). We introduce other significant macroeconomic variables in order to account their simultaneity of impact. In estimating our panel data growth regressions with country-specific and time-specific fixed effects, we are

motivated by Islam (1995), which allows us to estimate the impact of a change in any one factor on growth within a country in the data panel.

$$\text{GDPgrowth}_t^j = \alpha + \beta \text{GDP}_{t-1}^j + \gamma \text{debt}_t^j + \phi(\text{gfcf}_t^j, \text{fce}_t^j, \text{tgdp}_t^j, \text{gfc}_t^j, \text{fdi}_t^j) + \mu_j + \nu_t + \varepsilon_{jt} \quad \text{----- Eqn (2)}$$

Where μ_j is country fixed effects; ν_t is time fixed effects; ε_{jt} is the error term.

3. The augmented Solow growth regression model

We extend our econometric specification using a Solow growth model. Following this model, our specification assumes that the structural growth for country 'j' conforms to a linear relationship over a period 't' and is common across the panel of countries.

$$\begin{aligned} \text{GDPgrowth}_t^j &= \beta^{\wedge} X_t^j + \mu_j + \nu_t + \varepsilon_{jt} \\ \text{GDPgrowth}_t^j &= \beta_s^{\wedge} S_j + \gamma \text{debt}_t^j + \mu_j + \nu_t + \varepsilon_{jt} \end{aligned} \quad \text{----- Eqn (3)}$$

Where S_j is a vector of Solow regressors including gfcf, gfc, tgdp, fce, fdi, infl, lagged GDP, pg, and adr. It also includes the constant. μ_j is country-specific fixed effects; ν_t is time-fixed effects; ε_{jt} is the unobservable error term. Given the strong potential for endogeneity of the debt variable, we use the instrumental variable (IV) estimation technique. In our instrumental variables model, we use Solow instruments in their lagged variables. As Easterly and Rebelo (1993) observe, one of the most likely sources of simultaneity is business cycle effects and the tendency of government expenditure to be positively correlated with the level of GDP per capita. Many studies on growth regressions exploring panel data have made use of the IV approach to deal with the issue of simultaneity bias (see Hiebert et al. 2002). With the use of GMM estimator, we seek to correct for the possible heteroscedasticity and autocorrelation in the error structure by using the consistent estimator. The two-step GMM provides some efficiency gains over the traditional IV/2-SLS estimator derived from the use of the optimal weighting matrix (Baum et al. 2013).

4. Testing for non-linearity

In the debt–growth dynamics literature, the non-linearity of the impact of debt on economic growth has been examined in different specifications. Reinhart and Rogoff (2010) use the correlations between debt and growth. On the other hand, Kumar and Woo (2012) and Egert (2015) study the relationship using the growth framework. While many empirical papers identify non-linearities in the relationship between debt and growth, very few studies make a clear theoretical argument for the presence of such non-linearities (Greiner 2013).

We investigate the non-linearity of the debt-growth relationship (in view of the negative correlations at higher levels of debt with growth) by considering a specification that accounts

for the polynomial trend of the debt variable. To introduce the smooth transition around a turning point in debt level, in its impact on economic growth, we transform the Eqn (3) to formulate the following specification by introducing a square term of the debt to GDP ratio as an additional regressor:

$$\text{GDPgrowth}_t^j = \beta_s \hat{S}_i + \gamma \text{debt}_t^j + \gamma^2 \text{debt}_t^{2j} + \mu_j + \nu_t + \varepsilon_{jt} \quad \text{----- Eqn (4)}$$

Robustness checks

In order to ensure that the outliers do not influence the results, we identify the outliers by drawing the scatter plot of the partial correlation between debt and growth obtained with the IV regression and estimate the models by dropping them. We also employ robust least squares (RLS) regression method designed to be robust, or less sensitive to outliers. We use the M-estimation method of RLS. Using the Huber–White sandwich correction, serially correlated residuals are dealt with in the context of the presence of within-country time dependence and heteroscedasticity of unknown form. An alternative approach of using the Newey and West estimator that allows modeling the autocorrelation process in the error term is also employed. The method of PCSEs (suggested by Beck and Katz) is very robust when there is little or no correlation between unit effects and explanatory variables. It is argued that its performance declines as the correlation strengthens. We use the fixed effects estimator with robust standard errors that appears to do better in these situations (Kristensen and Wawro 2003).

5 RESULTS AND DISCUSSION

We begin our discussion of the results with the descriptive statistics approach (as relied upon by Reinhart and Rogoff (2010)) In Figure 6.1, we first provide a comparative analysis of the growth in different debt regimes comparable to those of Reinhart and Rogoff. It is interesting to note that as the debt regimes rise there is a decrease in the growth levels. We notice a higher growth (mean 5.06 and median 4.83) in the debt regime of 0-30 percent of GDP and gradually decreasing in subsequent higher debt regimes. Growth levels in terms of both the mean (1.86) and median (1.88) are abysmally low in the debt regime of 91-150 percent of GDP. Especially, in a very high debt regime, of above 151 percent of debt to GDP, the growth is negative (mean -1.08 and median -1.32).

Reinhart and Rogoff observe that the difference in median growth rates of GDP between low debt (below 30 percent of GDP) and high debt (above 90 percent of GDP) groups is 2.6 percentage points in advanced economies over the period. On a similar comparison, we find that for our full sample, the difference in the median growth rates of GDP between low debt regime (below 30 percent of GDP) and high debt regime (91-150 percent of GDP) is 2.95 percentage points. The difference in the median growth rates of GDP between low debt regime (below 30 percent of GDP) and very high debt regime (above 151 percent of GDP) is

6.15 percentage points. RR state that the difference in average growth rates between low and high debt is even larger (4.2 percentage points) for the advanced economies. Our study finds that the difference in average growth rates between low debt (below 30 percent of GDP) and high debt (91-150 percent of GDP) groups is 3.2 percentage points. The difference in average growth rates between low debt (below 30 percent of GDP) and very high debt (above 151 percent of GDP) groups is 6.14 percentage points.

Figure 6 Growth in debt regimes

We present in Figure 6.1 the GDP growth and median inflation in the debt regimes comparable to that of RR's categories. The number of observations in our sample (in RR sample) in the first four regimes is 160 (443), 620 (442), 400 (199) and 260 (96), for a total of 1440 (1180) observations. Our fifth debt regime of >151% is having 80 observations. In Figure 6.2 we present summary relationship of GDP growth and median inflation in the four groupings out of the full sample comparable to RR's four categories. In Figure 6.3 we present Reinhart and Rogoff's results.

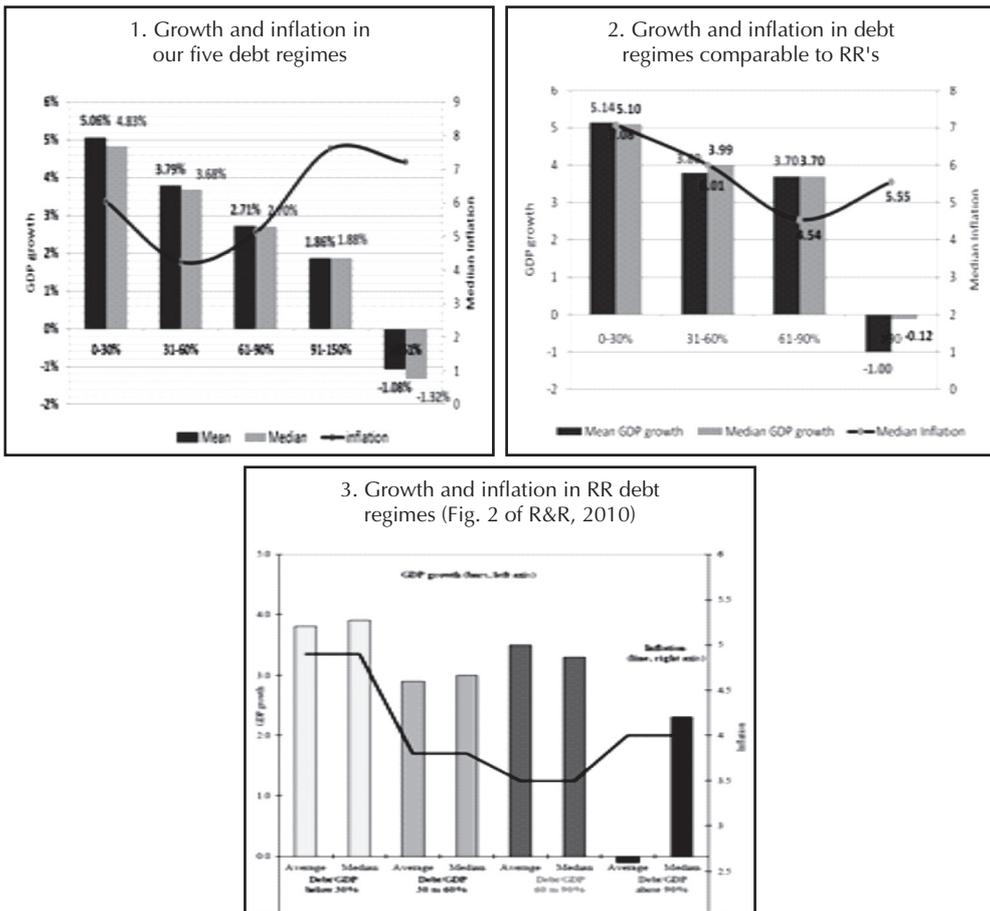

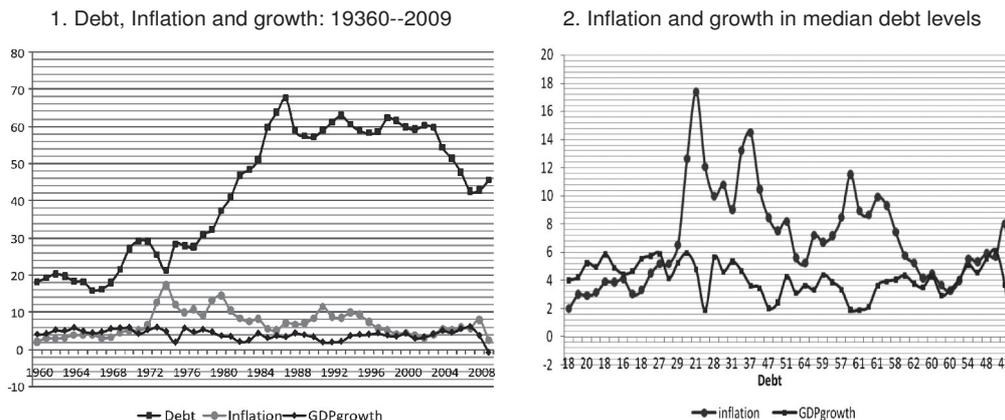

Figure 7 Debt, Inflation and Growth

We find inflation not necessarily influencing high debt levels across countries (Figure 7). The median debt levels have soared particularly during 1980-2000. However, the inflation levels have not experienced drastic and noticeable rise during the corresponding period. Median inflation and median GDP growth have mostly moved in tandem during the corresponding debt levels during 1960-2009 (Figure 7.2). The interaction of government debt with growth in the full sample suggesting the negative relationship is presented in Figure 8.

We provide in Figure 9 a discrete graphical analysis of the correlation between debt and growth in the debt regimes. In the debt regimes – 0-30%, 31-60% and 61-90%, the GDP growth hovers in the positive level and tends to fall into the negative zone in the debt regime – 91-150%. In the debt regime >151%, the GDP growth runs in the negative zone demonstrating debt intolerance.

Figure 8 Government debt and economic growth

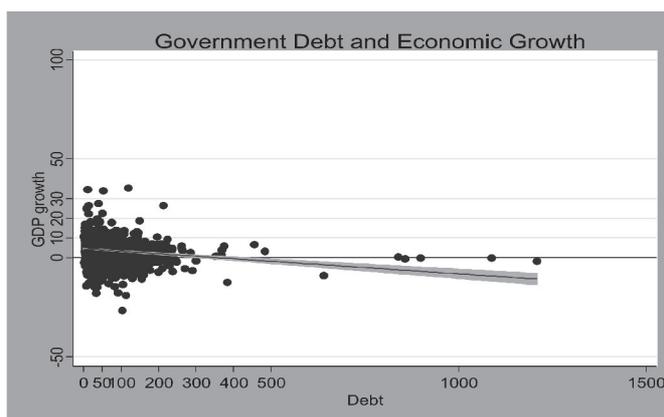

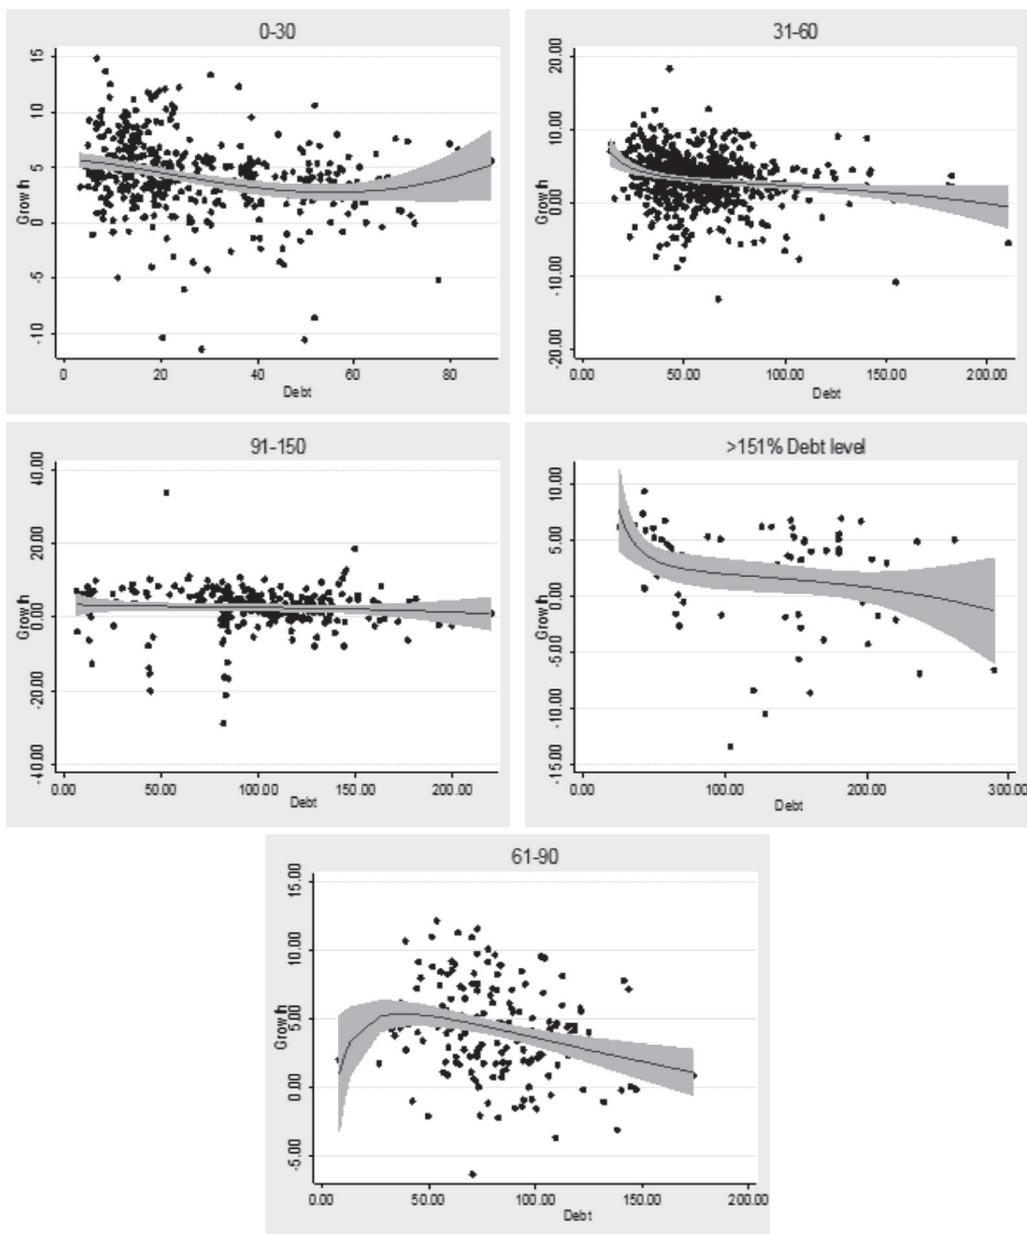

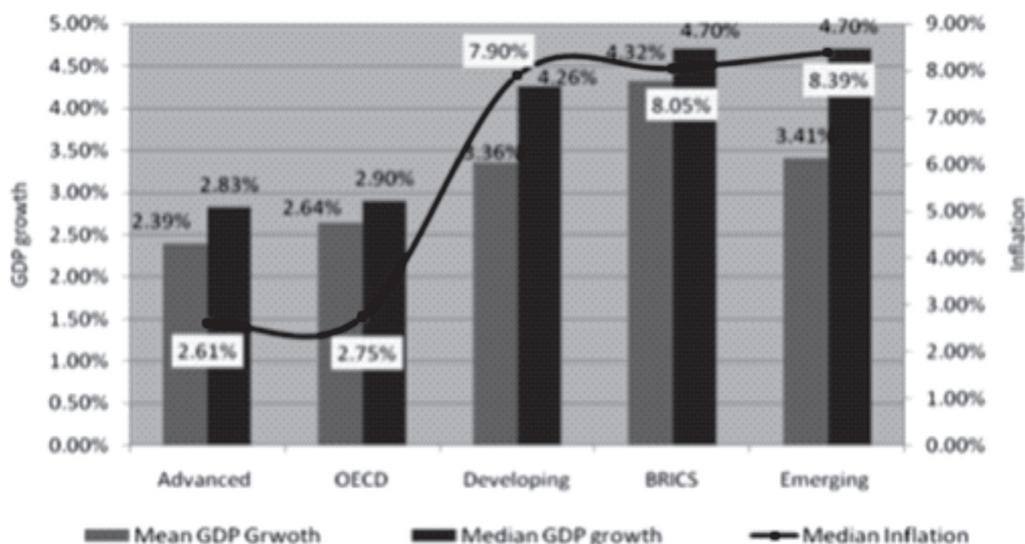

Figure 9 Government Debt and Growth in debt Regimes

This figure presents the dynamics of government debt and economic growth in debt regimes: 0-30; 31-60; 61-90; 91-150; 151 % above for the period from 1960-2009.

Analysis of inflation–growth nexus in the economy groupings reveals highest growth (mean 4.32 and median 4.70) in BRICS economies with mean debt 46.65 and median debt 46.79 (Figure 10). Further, a higher growth (mean 3.41 and median 4.70) is observed in emerging economies with (mean debt 43.73 and median debt 41.35). Developing economies experience average growth 3.36% (median growth 4.26%) with mean debt level 71.63 (median debt 56.67). OECD economies experience average growth 2.64% (median growth 2.90%) with mean debt level 55.17 (median debt 51.61). We notice advanced economies experiencing average growth 2.39% (median growth 2.83%) with mean debt 57.12 (median debt 53.38).

Figure 10 Inflation and Growth in Economy groupings

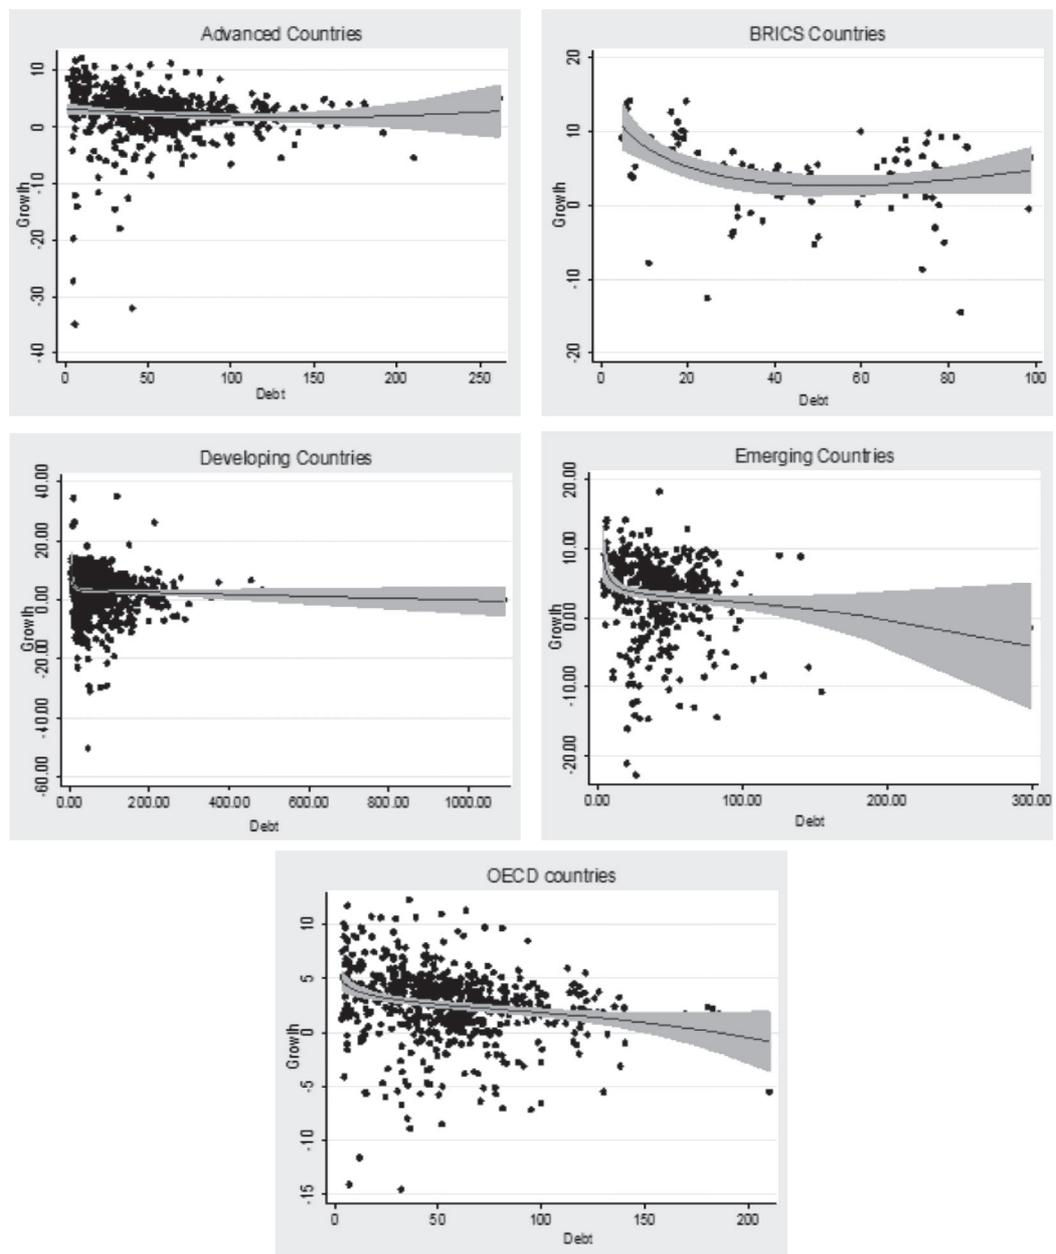

We notice that the difference in median growth rates of GDP between low debt group (emerging economies) and high debt group (advanced economies) is 1.87 percentage points. On a similar comparison, the difference in the median growth rates of GDP between emerging economies and BRICS economies is 0.01, between emerging economies and OECD economies, it is 1.81, and between emerging economies and developing economies it is 0.45 percentage points.

We present our analysis of the correlation between debt and growth in our five broad economy groupings more discretely in Figure 11. Advanced and OECD economies experience growth that shows positive correlation in contrast to the negative correlation observed in developing and emerging economies. BRICs economies exhibit unique behaviour and need greater attention for analysis.

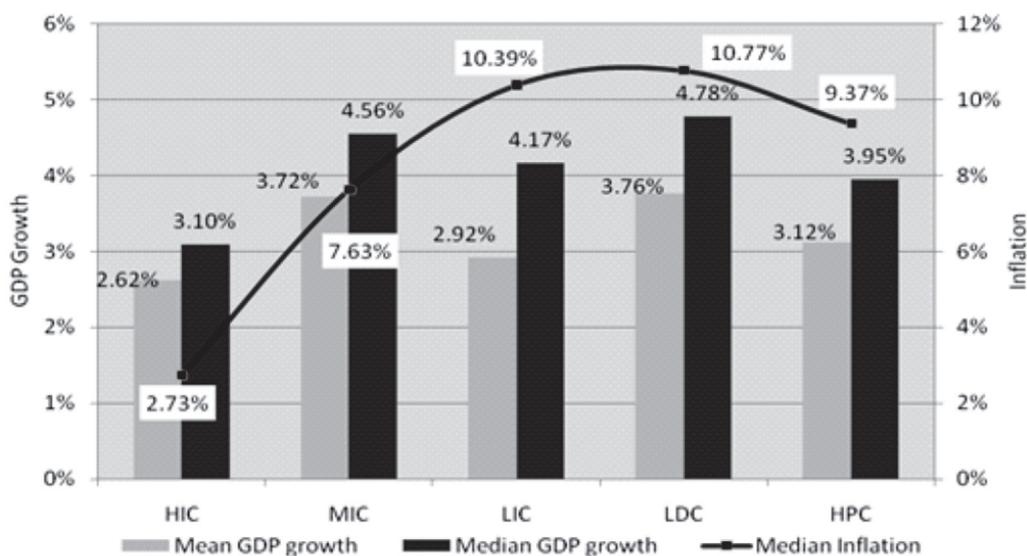

Figure 11 Government debt and growth in economy groups

This figure presents the dynamics of government debt and economic growth in economy groupings: advanced countries, BRICS, developing countries, emerging countries, and OECD countries during the period 1960-2009.

Analysis of inflation–growth nexus in the Income groupings is provided in Figure 12. We notice highest growth (mean 3.76 and median 4.78) in the LDC group (mean debt 100.86 and median debt 81.39) associated with a median inflation of 10.77. Further, higher growth (mean 3.72 and median 4.56) is observed in MIC group (mean debt 52.17 and median debt 42.73) associated with a median inflation of 7.63. The HPC group experiences average growth 3.12% (median growth 3.95%) with mean debt 124.10 (median debt 103.87) and median inflation 9.37%. The LIC group experiences average growth 2.92% (median growth 4.17%) with mean debt 91.37 (median debt 87.06). We notice HIC group experiencing average growth 2.62% (median growth 3.10%) with mean debt 49.99 (median debt 45.89) and median inflation 2.73%. The difference in median growth rates of GDP between low debt group (HIC) and high debt group (HPC) is 0.85 percentage points. Median inflation for the different debt groupings based on incomes suggests an apparent pattern—inflation levels move upward from high-income countries to low income countries.

Figure 12 Inflation and Growth in Income groupings

We illustrate in Figure 13 the interplay between debt and growth in our income groupings. HIC and LDC groups experience growth that hovers much in the positive levels in contrast to that in LIC and HPC groups where the growth tends to slide into the negative zone demonstrating the debt intolerance as they go through high debt levels. LDC group displays a distinct behaviour, which deserves in depth analysis.

Figure 13 Government debt and growth in income groups

This figure presents the dynamics of government debt and economic growth in income groupings: high-income countries (HIC), highly indebted poor countries (HPC), least developed countries (LDC), low-income countries (LIC), and middle-income countries (MIC) during the period 1960-2009.

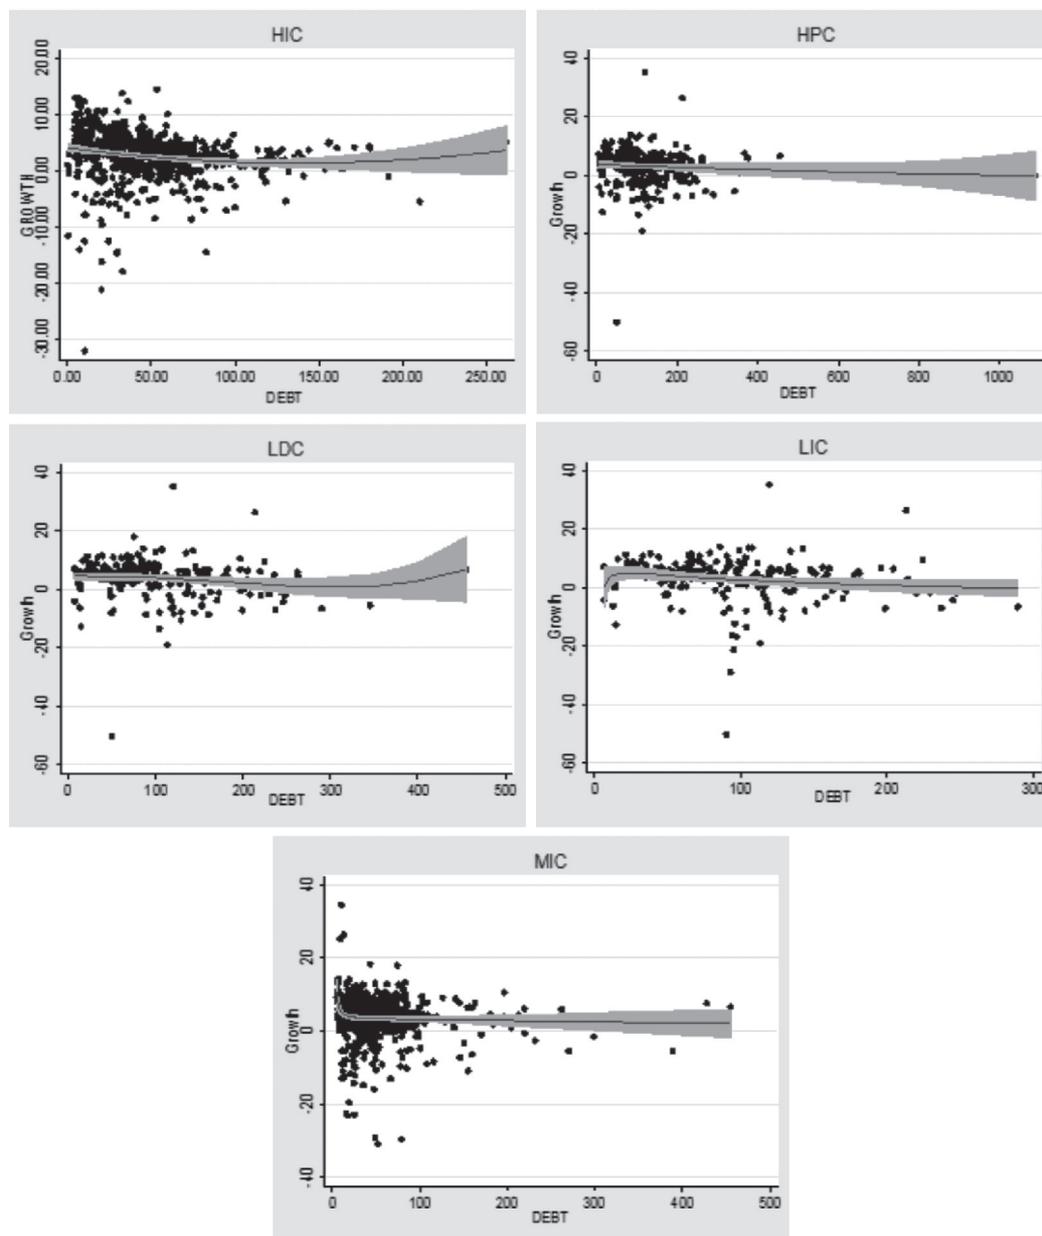

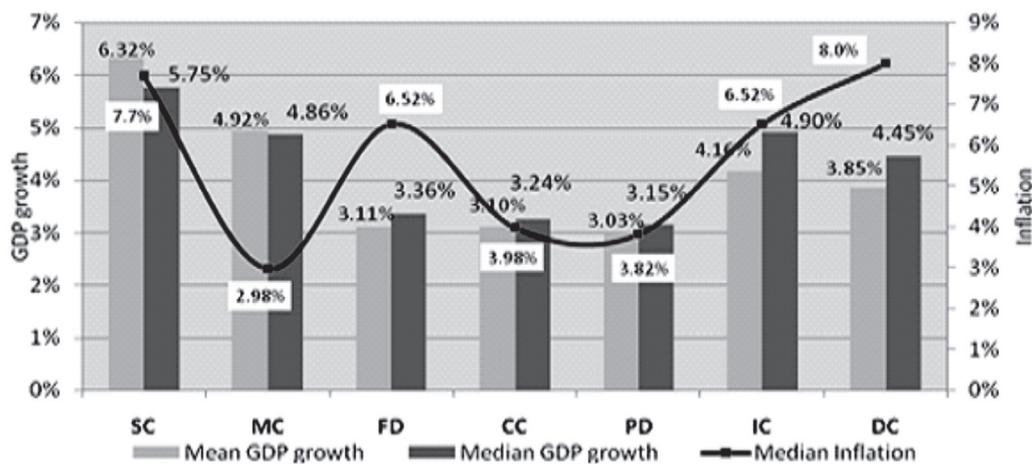

Figure 14 illustrates the interesting facts of the dynamics of government debt, inflation, and growth in different political economies. Socialist/communist (SC) countries with highest growth rates (mean 6.32 and median 5.75) and lowest debt level (mean debt 36.44 and median 18.74) among the compared categories experience median inflation of 7.7 percent. On the contrary, parliamentary democracies (PD) experience lowest growth rate (mean 3.03 and 3.15) with mean debt 67.81 (median debt 65.12) are associated with lowest median inflation of 3.82 percent. Monarchy countries (MC) experience lowest debt level (mean debt 40.31 and median debt 23.61) experience mean GDP growth 4.92 (median 4.86) and lowest median inflation 2.98 percent. In contrast, dictatorship countries (DC) experience highest debt level (mean debt 87.63 and median debt 69.63) with mean growth 3.85 (median 4.45) and highest median inflation 8 percent. Apparently, we do not notice a specific pattern.

Figure 14 Debt, Inflation and Growth in Political governance groupings

Islamic countries (IC) experience average growth 4.16% (median growth 4.90%) with mean debt 72.76 (median debt 64.76) and median inflation 6.52%. Coalition-governments countries (CC) with median inflation 3.98% are found to be associated with mean debt 66.24 (median debt 61.59) and mean growth rate 3.10% (median growth 3.24%). Federal democracies (FD) experience average growth 3.11% (median growth 3.36%) with mean debt 54.26 (median debt 54.83) associated with median inflation of 6.52%. The difference in median growth rates of SC (low debt group) and DC (high debt group) is 1.3-percentage point. We provide in Figure 15 the correlation between debt and growth in the political governance based groupings in detail. DC, MC, SC and IC political economies experience growth that hovers much in the positive levels in contrast to that in PD, CC and FD political economies where the growth tends to glide into the negative zone indicating debt intolerance as they go through higher debt/GDP levels.

Figure 15 Government debt and growth in political governance groupings

This figure presents the dynamics of government debt and economic growth in political governance groupings: Islamic countries (IC); coalition countries (CC); dictator led countries (DC); federal democracies (FD); monarchy countries (MC); parliamentary democracies (PD); and socialist countries (SC) during the period 1960-2009.

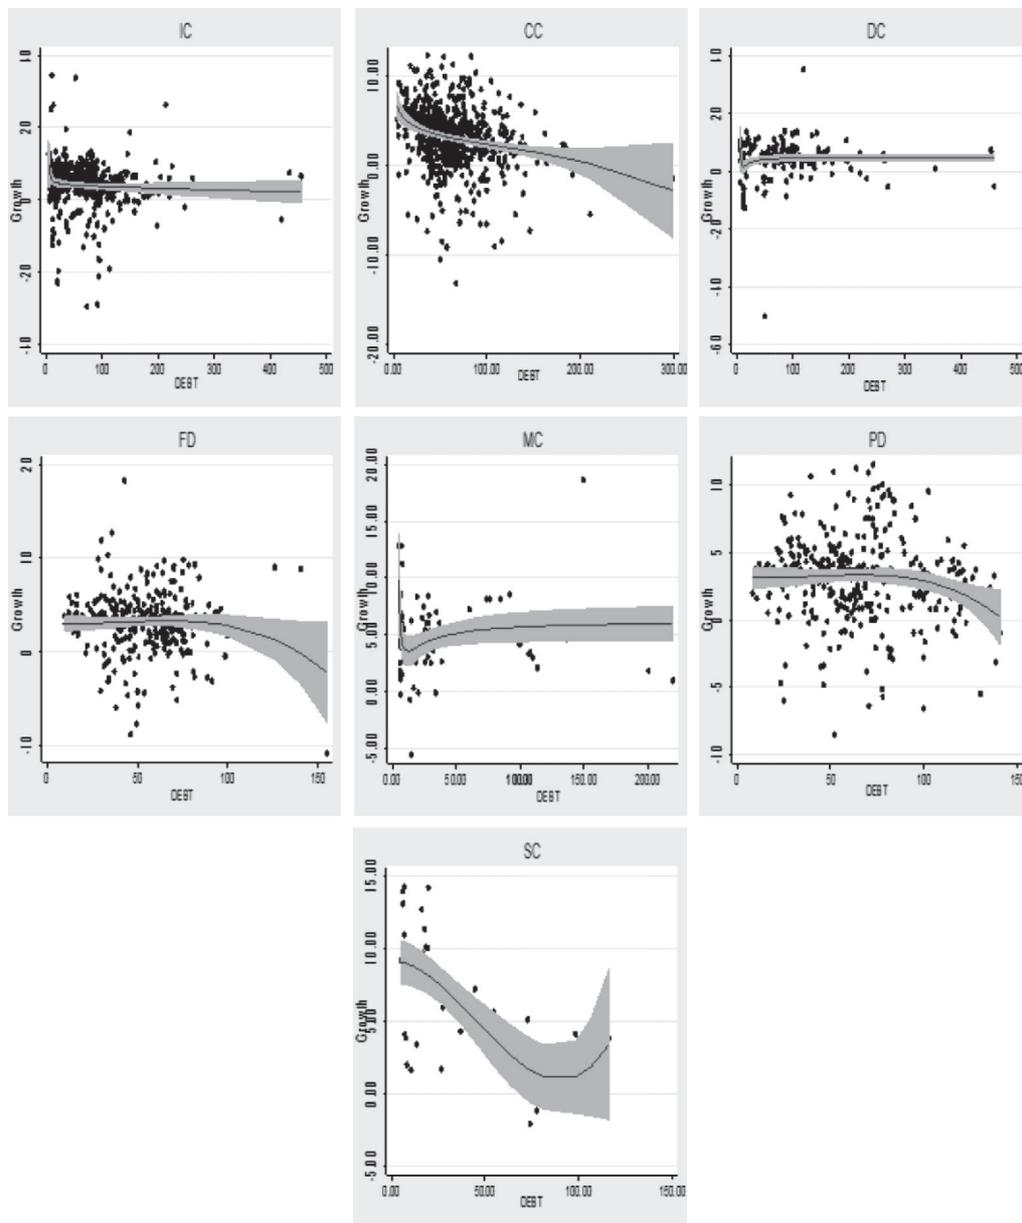

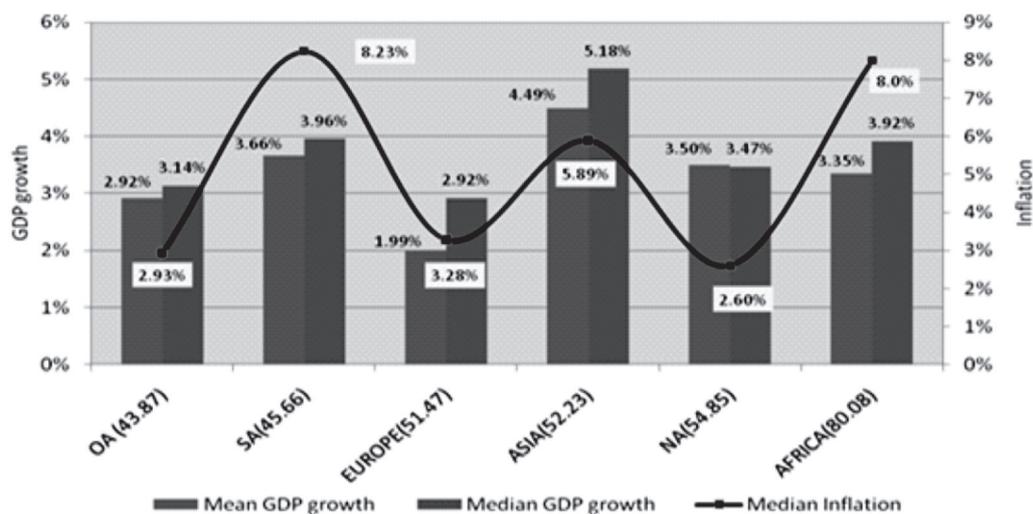

Figure 16 illustrates the dynamics of government debt, inflation and growth in different regional economies. Asia with highest mean growth rate 4.49 (median 5.18) and mean debt 57.36 (median debt 52.23) experiences median inflation 5.89 percent. On the contrary, Europe experiences lowest mean growth rate 1.99 (median 2.92) with mean debt 55.04 (median debt 51.47) and median inflation 3.28 percent. Oceania with lowest debt level (mean debt 42.39 and median debt 43.87) experiences mean growth 2.92 (median 3.14) and lowest median inflation 2.93 percent. On the contrary, Africa with highest debt level (mean debt 91.94 and median debt 80.08) experience mean growth 3.35 (median 3.92) and median inflation of 8 percent.

Figure 16 Inflation and growth in regional groupings

South America (SA) experiences average growth 3.66 (median growth 3.96) with mean debt 49.25 (median debt 45.66) and highest median inflation 8.23 percent. On the contrary, North America (NA) with lowest median inflation 2.60 experiences a mean growth 3.50 (median growth 3.47) associated with mean debt 57.45 (median debt 54.85). The difference in median growth rates of GDP between OA (low debt group) and Africa (high debt group) is 0.78 percentage point.

We provide in Figure 17 the correlation between debt and growth in regional groupings. Oceania and North America experience growth that hovers much in the positive levels in contrast to that in Asia, Africa, Europe, and South America where the growth tends to drift smoothly into the negative zone demonstrating the negative correlation as they experience higher debt levels.

Figure 17 Government debt and growth in regional groupings

This figure presents the dynamics of government debt and economic growth in regional groupings: Africa, Asia, Europe, North America, Oceania, and South America during the period 1960-2009.

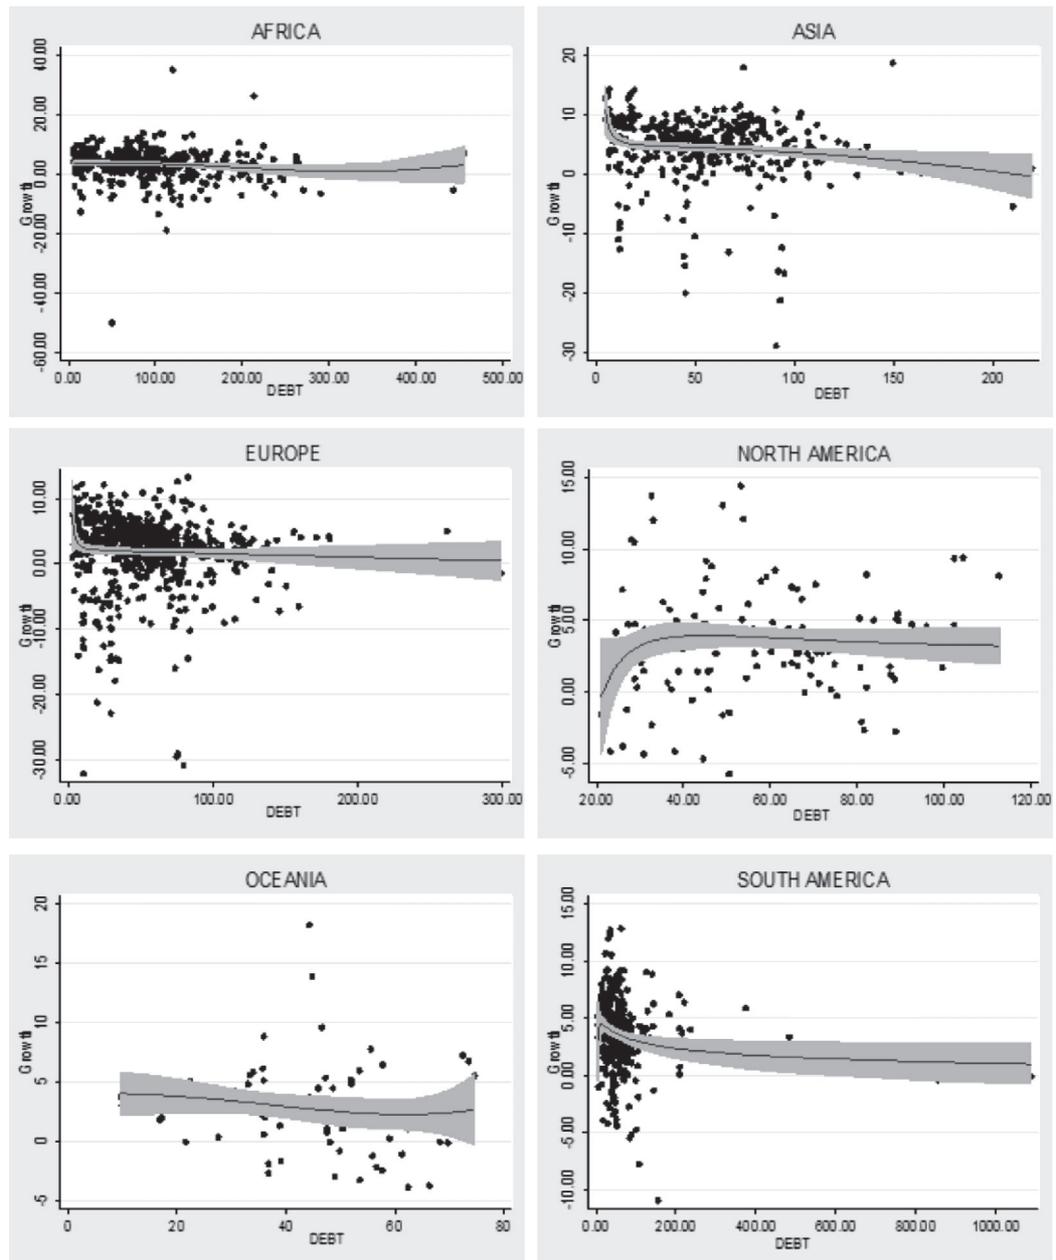

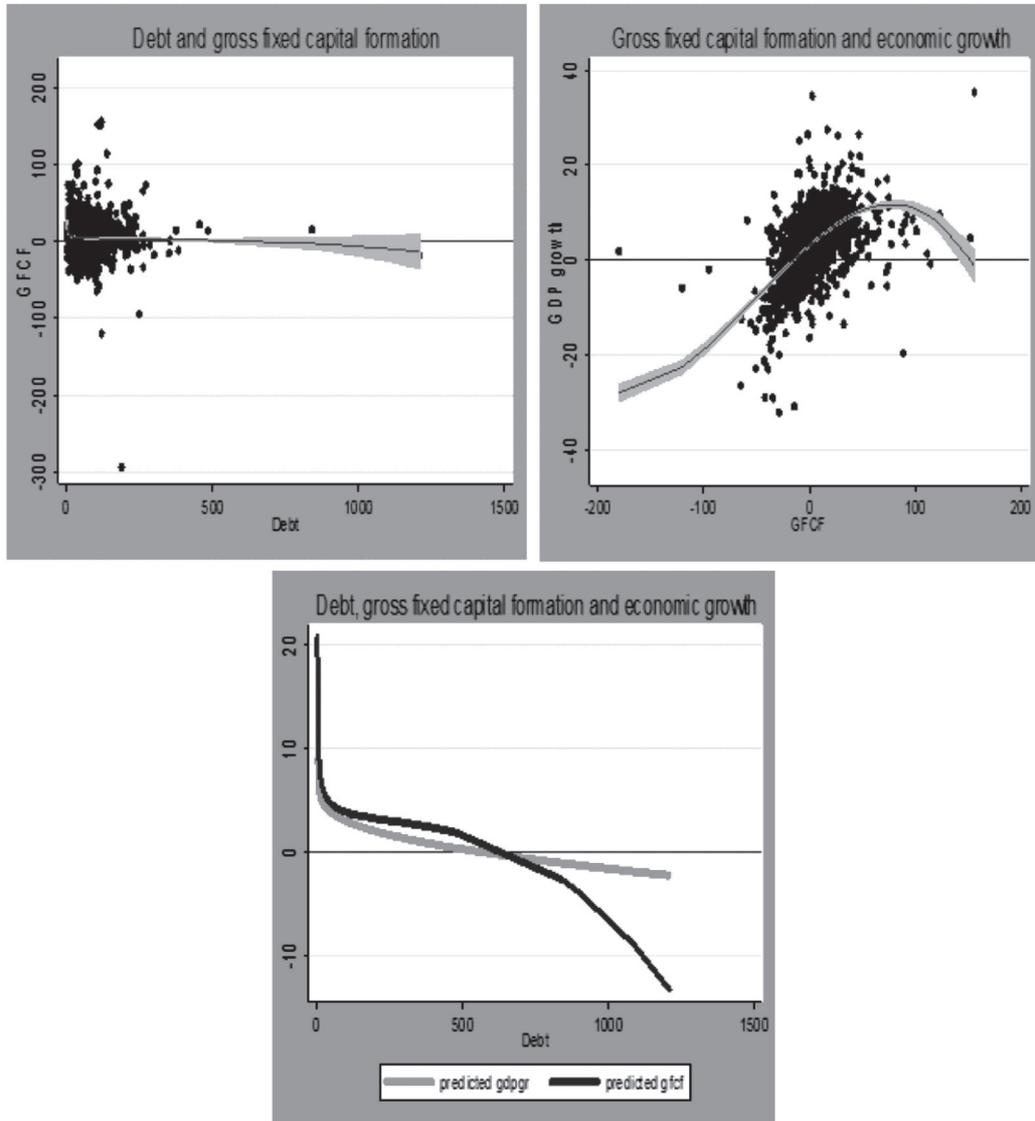

Table 7 Government debt and Economic Growth - Regression Results

This table presents the results of the regressions for understanding the effect of debt on the long-term growth of countries. Our dependent variable is the GDP growth. Columns (1), (2) and (5) present the results of the Panel Least Squares (PLS). Columns (3) and (6) present the results of the Panel Generalized Method of Moments (PGMM) (Cross-section weights (PCSE) standard errors & covariance). Columns (4), (5) and (7) present the results of Robust Least Squares. We report the coefficient values marked with significance levels in the first row followed by the standard errors (in the parenthesis) in the second row. Asterisks ***, ** indicate levels of significance at 1%, and 5% respectively.

Figure 18 Gross fixed capital formation as a causal link that goes through debt to growth as an instrumental variable

We present in the figures below the relationship between debt, gross fixed capital formation and economic growth. The first figure illustrates the association of gross fixed capital formation (GFCF) with debt. The second figure captures the relationship between GFCF and GDP growth that is similar to the relationship of debt with growth. The third figure presents the association of debt with GFCF and GDP growth. As debt increases, growth as well as GFCF decrease indicating a nonlinear relationship.

We now discuss the results of the econometric analysis of the debt-growth relationship encompassing the econometric specifications for (a) testing the bivariate relationship as modeled in Eqn. (2); (b) testing the linear relationship as modeled in Eqn. (3); (c) testing the augmented Solow growth model in Eqn. (4); and (d) testing for nonlinearity as modeled in Eqn. (5). Table 7 presents the results of the analyses. As observed in other studies as well, simple bivariate panel regression reveals a negative relation between growth and government debt. Though the coefficient is always negative, its size is mostly not substantial in economic terms. The results of the linear specifications suggest econometrically significant negative association of debt with growth. As we analyse the nonlinear models, the econometric significance as well as the coefficient value increase for debt in its relationship with economic growth.

We notice the causal link going from debt to growth through the instrumental variable – gross fixed capital formation (GFCF). The results of panel GMM regressions with IV approach suggest the significant role of GFCF in causing the relationship between debt and economic growth. Figure 18 further illustrates the intricate relationship. As debt increases, GDP growth as well as GFCF decrease indicating a nonlinear relationship.

The point estimates of the range of econometric specifications suggest that a 10-percentage point increase in the debt-to-GDP ratio is associated with 2 to 23 basis points reduction of average growth. Our results are comparable to the estimates of Kumar and Woo (2010) and Égert Balázs (2015) for advanced and emerging economies over almost four decades.⁷ Studying a sample of 17 OECD countries, Panizza and Presbitero (2014) observe that a 10-percentage point increase in the debt-to-GDP ratio is associated with an 18 basis point decline in average growth.

6 CONCLUSION

This study has presented a thorough analysis of the dynamics of government debt and economic growth as it spans regions, political economies, diverse economies, varied income groupings and different debt regimes. The sources on which the study draws are more authentic and well accepted. We do not claim that the results are infallible, but do state that they are based on widely accepted econometric tools and techniques besides based on sound economic logic. One of the contributions of this study is that it is the first of its kind in providing a meticulous analysis of debt and growth in different of groupings and sub-

Kumar and Woo (2010) report that on average, a 10-percentage-point-increase in the initial debt-to-GDP ratio is associated with a slowdown in annual real per capita GDP growth of around 0.2 percentage points per year. Égert Balázs (2015) report that 10 percentage increase in the government debt ratio is associated with 0.1 to 0.2 percentage point lower economic growth.

groupings of countries spanning across time period since 1960. The study enhances our understanding of the long-term dynamics of debt and economic growth in diverse economic environments and periods of recent history of economic activity. The study provides an original analysis of the debt and growth beyond the popular discourse mostly surrounding the advanced countries.

Debt in advanced and BRICS economies is rising steadily. Advanced economies experience lower rate of economic growth as they maintain higher levels of debt. On the other hand, emerging economies with lowest debt level experience higher rate of growth. Interestingly, BRICS countries as a distinct group experience highest rate of economic growth in spite of having moderate levels of debt. Economy groupings analysis does not provide any apparent pattern of the debt–growth relationship across the groups emphasising the existence of non-linear nature of relationship.

Heavily indebted poor countries with very high debt levels experience moderate economic growth. On the contrary, middle-income countries with lower levels of debt experience higher rate of economic growth. Coalition countries and federal democracies maintain higher level of debt and experience a moderate rate of economic growth. One immediate inference could be that due to the intricate dynamics of coalition politics and issues related to states and union, these countries suffer from lack of robust economic policies in relation to debt and growth. Perhaps the divergent political forces and philosophies fail to converge for a sound policy approach for debt management towards achieving higher economic growth. Despite having higher levels of debt, dictator-led countries experience higher rate of growth. Similar is the case with Islamic countries. Perhaps due to the long-standing dictatorial rulers and political stability in these countries, economic growth has been higher in spite of higher levels of government debt. One important take-away is that parliamentary democracies in spite of having higher debt levels than that of coalition countries and federal democracies, have failed to achieve higher rate of economic growth than that of these countries. Socialist/communist countries and monarchy countries are found to experience very high rate of economic growth as they maintain lower levels of government debt.

This study provides a clear understanding about the triad—debt, inflation, and growth—in the case of economy groupings. Emerging economies, developing economies and BRICS countries are found to experience higher levels of economic growth in spite of having higher levels of inflation. On the contrary, lower rate of economic growth in advanced and OECD economies is associated with lower levels of inflation. The analysis of income groupings suggests an apparent pattern—inflation levels move upward from high-income countries to low income countries. One interesting observation is that Islamic countries with the highest level of inflation have highest debt level. In line with the same logic, monarchy

countries that experience lowest inflation have lowest debt level. Amongst regional groupings, Africa with highest debt level is associated with high level of inflation. Oceania with lowest debt level is associated with low inflation. Thus, rising debt levels are positively associated with increasing levels of inflation.

To conclude, this study observes a negative relationship between government debt and growth. The point estimates of the range of econometric specifications suggest that a 10-percentage point increase in the debt-to-GDP ratio is associated with 2 to 23 basis point reduction in average growth. Our results establish the nonlinear relationship between debt and growth.
